

## ABSTRACT

A high-intensity discharge lamp connected to a lighting device has various superior emission properties such as efficiency.

5 The discharge lamp includes a translucent ceramic discharge vessel, in which a pair of electrodes and a discharge medium are inserted. The lamp further includes an outer jacket, in which the arc tube is disposed, and a pair of feeder members. The discharge medium has metal halides including those of Na, Tl and Tm or Na,

10 Tl, In and Tm, and the ratio ( $MT_m/M$ ) of the weight of the gross sealed mass  $M$  of the metal halides to the filled mass  $MT_m$  of the Tm halide is about  $0.4 \leq MT_m / M \leq 0.9$ . The deviation in chromaticity (d.u.v.) on the x-y chromaticity coordinates (CIE 1931) for the overall operating position during the life of the lamp is

15 within the range of about -0.006 to +0.010.
